

Coinfection: More than the sum of its parts

Complex interplay between humans, fungi and viruses

Jena. Infections with two pathogens pose a serious threat in the clinics. Researchers from Würzburg and Jena have developed a technique that provides new insights into this process and can be used as an early warning system.

Organ and stem cell transplants are proven and frequently used methods in everyday modern clinical practice. However, even when performed regularly in specialized centers, some patients still experience a number of serious complications afterwards. Among other things, infections with fungi and viruses can jeopardize therapeutic success. For example, coinfection with cytomegalovirus, which belongs to the family of Herpes viruses, and the fungus *Aspergillus fumigatus* can be critical. This combination of pathogens poses a serious medical threat in organ and stem cell transplantation.

When viruses and fungi join forces

A team of scientists from several German research institutions and clinics has now developed a new method to examine these two pathogens, their interaction with each other and with the human cells infected by them. The central result: coinfection with the two pathogens is more "than the sum of its parts". Viruses and fungi interact synergistically in the human organism, where they trigger certain genes that only become active when infected with both pathogens simultaneously.

The study involved scientists from the Julius Maximilian University of Würzburg (JMU), the Würzburg University Hospital (UKW), the Leibniz Institute for Natural Product Research and Infection Biology in Jena (Leibniz-HKI) and the Helmholtz Institute for RNA-based Infection Research (HIRI) in Würzburg, a site of the Braunschweig Helmholtz Centre for Infection Research (HZI). The results have now been published in the journal *Cell Reports*.

New insights thanks to a novel technology

"For our study, we have developed a method called Triple RNA-seq," explains Alexander Westermann. He is junior professor at the Chair of Molecular Infection Biology I at JMU, as well as group leader at the HIRI. Together with Jürgen Löfller from UKW and Sascha Schäuble from Leibniz-HKI he is one of the senior authors of the study. The scientists have advanced an established method that has been an integral part of infection research for years: dual RNA-seq.

The term "RNA-seq" is short for RNA-sequencing: This technique enables the simultaneous and precise determination of the activities of thousands of genes at the RNA level in a high-throughput process, thus enabling the identification and better understanding of the changes occurring in the course of diseases. The development of dual RNA sequencing has made it possible to document not only the gene activity of a pathogen, but also the reaction of the host cell affected by it. This

has enabled scientists to trace complex causal chains over the course of an infection.

Research on immune cells

Now, Triple RNA sequencing dissects the gene expression of three players and their interplay in infection processes. "Up to now, science has in many cases not known why an infection with a certain pathogen can make the affected person more susceptible to an infection with a second pathogen," explains Jürgen Löffler, molecular biologist at the Medical Clinic II of the UKW. In such cases, dual RNA-seq was insufficient to provide the desired answers.

In their study, the researchers used the triple RNA-seq method they developed to investigate what happens when certain cells of the immune system (known as monocyte-derived dendritic cells) are infected with both *Aspergillus fumigatus* and the human cytomegalovirus.

They were able to prove that the two pathogens influence each other, whilst also simultaneously affecting the immune cell in a different way than one pathogen alone otherwise would. For example, the cytomegalovirus weakened the fungal-mediated activation of pro-inflammatory signals, while *Aspergillus* affects viral clearance - the time it takes for the virus to become undetectable in tests.

Bioinformatic data analysis

The analysis of the RNA sequences using the new triple RNA seq method yielded immense amounts of data. The bioinformaticians of the Leibniz-HKI took on the task of evaluating these data and filtering out the information contained in them. For this purpose they developed and analysed so-called correlation networks. With the help of such networks, the scientists are able to identify, with statistical certainty, precisely those genes that control the complex interactions of the three partners - human, fungus and virus.

Hope for a biomarker

In this way, the team has identified specific genes in immune cells whose expression profiles differ significantly during an infection with both pathogens, compared to a single infection. These genes could thus serve as biomarkers for the timely identification of a co-infection after transplantation.

The scientists now hope that the triple RNA-seq technology will also help to better understand other cases of common infections, such as viruses and bacteria, and to prevent their potentially serious consequences. "Promising models for understanding how an infection makes the host more susceptible to another pathogen include certain strains of *Salmonella* and the human immunodeficiency virus (HIV), streptococci and influenza virus, or *Chlamydia* and human herpes virus," says Westermann. As a next step, Westermann plans to use the triple RNA-seq technique to investigate infections in which two different types of bacteria jointly influence the course of the disease.

Research within the network

The research results were made possible by the intensive cooperation of scientists in the Collaborative Research Centre/Transregio FungiNet. In this network, funded by the German Research Foundation, biologists, medical doctors and bioinformaticians from Jena and Würzburg are investigating the molecular mechanisms of fungal infections in humans. A deeper understanding of the infection processes and the response of the human immune system should help to identify such infections more quickly and treat them successfully in the future.

Das Leibniz-HKI

Das Leibniz-Institut für Naturstoff-Forschung und Infektionsbiologie – Hans-Knöll-Institut – wurde 1992 gegründet und gehört seit 2003 zur Leibniz-Gemeinschaft. Die Wissenschaftler des Leibniz-HKI befassen sich mit der Infektionsbiologie human-pathogener Pilze. Sie untersuchen die molekularen Mechanismen der Krankheitsauslösung und die Wechselwirkung mit dem menschlichen Immunsystem. Neue Naturstoffe aus Mikroorganismen werden auf ihre biologische Aktivität untersucht und für mögliche Anwendungen als Wirkstoffe zielgerichtet modifiziert.

Das Leibniz-HKI verfügt über sechs wissenschaftliche Abteilungen und vier Forschungsgruppen, deren Leiter überwiegend berufene Professoren der Friedrich-Schiller-Universität Jena sind. Hinzu kommen mehrere Nachwuchsgruppen und Querschnittseinrichtungen mit einer integrativen Funktion für das Institut, darunter das anwendungsorientierte Biotechnikum als Schnittstelle zur Industrie. Gemeinsam mit der FSU betreibt das HKI die [Jena Microbial Resource Collection](#), eine umfassende Sammlung von Mikroorganismen und Naturstoffen. Zurzeit arbeiten etwa 450 Personen am Leibniz-HKI, davon 150 Promovierende.

Das Leibniz-HKI ist Kernpartner großer Verbundvorhaben wie dem Exzellenzcluster [Balance of the Microverse](#), der Graduiertenschule [Jena School for Microbial Communication](#), der Sonderforschungsbereiche [FungiNet](#) (Transregio), [ChemBioSys](#) und [PolyTarget](#), des Zentrums für Innovationskompetenz [Septomics](#) sowie von [InfectControl 2020](#), einem Konsortium im BMBF-Programm Zwanzig20 – Partnerschaft für Innovation. Das Leibniz-HKI ist zudem [Nationales Referenzzentrum für invasive Pilzinfektionen](#).

Die Leibniz-Gemeinschaft

Die Leibniz-Gemeinschaft verbindet 96 selbständige Forschungseinrichtungen. Ihre Ausrichtung reicht von den Natur-, Ingenieur- und Umweltwissenschaften über die Wirtschafts-, Raum- und Sozialwissenschaften bis zu den Geisteswissenschaften.

Leibniz-Institute widmen sich gesellschaftlich, ökonomisch und ökologisch relevanten Fragen. Sie betreiben erkenntnis- und anwendungsorientierte Forschung, auch in den übergreifenden Leibniz-Forschungsverbünden, sind oder unterhalten wissenschaftliche Infrastrukturen und bieten forschungsbasierte Dienstleistungen an. Die Leibniz-Gemeinschaft setzt Schwerpunkte im Wissenstransfer, vor allem mit den Leibniz-Forschungsmuseen. Sie berät und informiert Politik, Wissenschaft, Wirtschaft und Öffentlichkeit.

Leibniz-Einrichtungen pflegen enge Kooperationen mit den Hochschulen - in Form der Leibniz-WissenschaftsCampi, mit der Industrie und anderen Partnern im In- und Ausland. Die Leibniz-Institute unterliegen einem transparenten und unabhängigen Begutachtungsverfahren. Aufgrund ihrer gesamtstaatlichen Bedeutung fördern Bund und Länder die Institute der Leibniz-Gemeinschaft gemeinsam. Die Leibniz-Institute beschäftigen rund 20.000 Personen, darunter 10.000 Wissenschaftlerinnen und Wissenschaftler. Das Finanzvolumen liegt bei 1,9 Milliarden Euro.
